(54) Title: ELECTROSURGICAL DEVICE FOR NECROSIS INDUCTION

(57) Abstract

A cell necrosis apparatus includes an introducer with a distal end sufficiently sharp to penetrate tissue. An energy delivery device has a first set of RF electrodes, a second set of RF electrodes and a third RF electrode. Each of the electrodes has a tissue piercing distal end and is positional in the introducer as the introducer is advanced through tissue. The first and second sets of RF electrodes are deployable with curvature from the introducer. The third RF electrode is deployable from the introducer with less curvature than the first and second sets of RF electrodes. The second set of RF electrodes is deployable a greater distance from the introducer than the first set of RF electrodes.

ELECTROSURGICAL DEVICE FOR NECROSIS INDUCTION

BACKGROUND OF THE INVENTIONField of the Invention

5 This invention relates generally to a cell necrosis apparatus, and more particularly to a cell necrosis apparatus with an introducer and deployable electrodes.

Description of the Related Art

10 Current open procedures for treatment of tumors are extremely disruptive and cause a great deal of damage to healthy tissue. During the surgical procedure, the physician must exercise care in not cutting the tumor in a manor that creates seeding of the tumor, resulting in metastasis. In recent years, development of products has been directed with an emphasis on minimizing the traumatic nature of traditional surgical procedures.

15 There has been a relatively significant amount of activity in the area of hyperthermia as a tool for treatment of tumors. It is known that elevating the temperature of tumors is helpful in the treatment and management of cancerous tissues. The mechanisms of selective cancer cell eradication by hyperthermia are not completely understood. However, four cellular effects of hyperthermia on cancerous tissue have been proposed, (i) changes in cell
20 or nuclear membrane permeability or fluidity, (ii) cytoplasmic lysosomal disintegration, causing release of digestive enzymes, (iii) protein thermal damage affecting cell respiration and the synthesis of DNA or RNA and (iv) potential excitation of immunologic systems. Treatment methods for applying heat to tumors include the use of direct contact radio-frequency

(RF) applicators, microwave radiation, inductively coupled RF fields, ultrasound, and a variety of simple thermal conduction techniques.

Among the problems associated with all of these procedures is the requirement that highly localized heat be produced at depths of several centimeters beneath the surface of the skin.

Attempts to use interstitial local hyperthermia have not proven to be very successful. Results have often produced nonuniform temperatures throughout the tumor. It is believed that tumor mass reduction by hyperthermia is related to thermal dose. Thermal dose is the minimum effective temperature applied throughout the tumor mass for a defined period of time. Because blood flow is the major mechanism of heat loss for tumors being heated, and blood flow varies throughout the tumor, more even heating of tumor tissue is needed to ensure effective treatment.

The same is true for ablation of the tumor itself through the use of RF energy. Different methods have been utilized for the RF ablation of masses such as tumors. Instead of heating the tumor it is ablated through the application of energy. This process has been difficult to achieve due to a variety of factors including, (i) positioning of the RF ablation electrodes to effectively ablate all of the mass, (ii) introduction of the RF ablation electrodes to the tumor site and (iii) controlled delivery and monitoring of RF energy to achieve successful ablation without damage to non-tumor tissue.

Thus, non-invasive procedures for providing heat to internal tissue have had difficulties in achieving substantial specific and selective treatment.

Examples illustrating the use of electromagnetic energy to ablate tissue are disclosed in: U.S. Patent No. 4,562,200; U.S. Patent No.

4,411,266; U.S. Patent No. 4,838,265; U.S. Patent No. 5,403,311; U.S. Patent No. 4,011,872; U.S. Patent No. 5,385, 544; and U.S. Patent No. 5,385,544.

5 There is a need for a cell necrosis apparatus with at least two electrodes that are deployable with curvature from an introducer. There is another need for a cell necrosis apparatus with at least two electrodes that are selectably deployable with curvature from an introducer to a desired deployed geometric configuration. There is yet a further need for a cell necrosis apparatus that provides deployable electrodes that create a variety
10 of different geometric cell necrosis lesions.

SUMMARY OF THE INVENTION

Accordingly, an object of the invention is to provide a cell necrosis apparatus that provides tissue reduction at selected anatomical sites.

5 Another object of the invention is to provide a treatment apparatus to create cell necrosis.

Still another object of the invention is to provide a cell necrosis apparatus that has at least two electrodes which are deployable from an introducer with curvature and a third electrode which is deployable with minimal curvature.

10 Yet another object of the invention is to provide a cell necrosis apparatus with selectively deployed electrodes.

A further object of the invention is to provide a cell necrosis apparatus that is configured to deploy electrodes selectively at a tissue site to create a desired cell necrosis lesion.

15 These and other objects of the invention are achieved in a cell necrosis apparatus including an introducer with a distal end sufficiently sharp to penetrate tissue. An energy delivery device has a first set of RF electrodes, a second set of RF electrodes and a third RF electrode. Each of electrodes has a tissue piercing distal end and is positionable in the
20 introducer as the introducer is advanced through tissue. The first and second sets of RF electrodes are deployable with curvature from the introducer. The third RF electrode is deployable from the introducer with less curvature than the first and second sets of RF electrodes. The second set of RF electrodes is deployable a greater distance from the introducer than
25 the first set of RF electrodes.

In another embodiment, a cell necrosis apparatus has an energy delivery device that includes a first RF electrode with a tissue piercing distal

portion and a second RF electrode with a tissue piercing distal portion. The first and second RF electrodes are positionable in the introducer as the introducer is advanced through tissue and deployable with curvature from the introducer at a selected tissue site. A groundpad electrode is coupled to the first and second RF electrodes. A first sensor is coupled to the groundpad electrode.

15

DETAILED DESCRIPTION

Referring to Figure 1, one embodiment of a cell necrosis apparatus 10 includes an introducer 12 with a distal end 14 sufficiently sharp to penetrate tissue. An energy delivery device, generally denoted as 16, includes a first RF electrode 18 and a second RF electrode 20. Electrodes 18 and 20 are positionable in introducer 12 as introducer 12 advances through tissue. Electrodes 18 and 20 have tissue piercing distal ends 22 and 24, respectively. Electrodes 18 and 20 are selectably deployed with curvature from a distal end 14 or a side port formed in a distal portion 26 of introducer 12 to a selected tissue site 28. Tissue site 28 can be any tissue mass and can be a tumor to be ablated. Electrodes 18 and 20 are selectably deployed to be controllably positioned at a desired location relative to tissue

site 28 that includes internal placement, external placement at a periphery of tissue site 28 and at any desired location relative to tissue site 28. The selectable deployment of electrodes 18 and 20 can be achieved with the amount of advancement of electrodes 18 and 20 from introducer 12, independent advancement of electrodes 18 and 20 from introducer 12, the lengths and/or sizes of energy delivery surfaces of electrodes 18 and 20, the variation in materials used for electrodes 18 and 20 as well as variation of geometric configuration of electrodes 18 and 20 in their deployed states.

Electrodes 18 and 20 are in compacted positions while they are positioned in introducer 12. As electrodes 18 and 20 are advanced from introducer 12 they move to a deployed state from their compacted configurations. Any number of electrodes can be included in energy delivery device 16. The electrodes of energy delivery device 16 can be deployed simultaneously, in pairs, in sets and one at a time. An electrode advancement member 30 is coupled to energy delivery device 16. Electrode advancement member 30 can be actuated by the physician by movement of a proximal end 32 relative to a longitudinal axis of introducer 12.

Introducer 12 can be flexible. In one embodiment, introducer 12 is sufficiently flexible to pierce tissue, and move in any desired direction through tissue to tissue site 28. In another embodiment, introducer 12 is sufficiently flexible to reverse its direction of travel and move in direction back upon itself. In one embodiment, introducer 12 is more flexible than electrodes 18 and 20.

When introducer 12 reaches tissue site 28, including but not limited to a solid lesion, energy delivery device 16 is deployed preferably from distal end 14 of introducer 12. Energy delivery device 16 can also be deployed from side ports formed in the body of introducer 12. In the

deployed state energy delivery device 16 becomes expanded from its compacted configuration in introducer 12 and is selectively positioned relative to tissue site 12. Electrodes 18 and 20 can be positioned within an interior of tissue site 12, at the exterior of tissue site 12 as well as combinations thereof. Electrodes 18, 20 as well as third, fourth, fifth, etc. electrodes are advanceable different lengths from distal end 14 of introducer 12. In one embodiment, the electrodes of deployed energy delivery device 16 are positioned equally distant a central axis of tissue site 28. Volumetric cell necrosis can proceed from the interior, exterior of tissue site 28 as well as various combinations thereof with each deployed electrode of energy delivery device 16 in order to create a selectable and predictable cell necrosis.

Electrodes 18 and 20 can be made of a variety of conductive materials, both metallic and non-metallic. One suitable material is type 304 stainless steel of hypodermic quality. In some applications, all or a portion of electrodes 18 and 20 can be made of a shaped memory metal, such as NiTi, commercially available from Raychem Corporation, Menlo Park, California. A radiopaque marker 21 can be coated on electrodes 18 and 20 for visualization purposes.

Electrodes 18 and 20 can have different lengths that are advanced from distal end 14 of introducer 12. The lengths can be determined by the actual physical length of electrodes 18 and 20, the length of an energy delivery surface of electrodes 18 and 20 and the length of electrodes 18 and 20 that is not covered by an insulator. Suitable lengths include but are not limited to 17.5 cm, 25.0 cm. and 30.0 cm. The actual lengths of electrodes 18 and 20 depends on the location of tissue site 28 to be ablated, its distance

from the skin, its accessibility as well as whether or not the physician chooses a laparoscopic, percutaneous or other procedure.

A deployable member 34 can be coupled to electrode advancement member 30. Deployable member 34 can provide a variety of different functions including but not limited to the placement of a sensor at a selected tissue site to measure/monitor temperature and/or impedance. Additionally, all or a portion of deployable member 34 can be an RF electrode operable in bi-polar or mono-polar modes. Deployable member 34 can also be a groundpad electrode.

A sensor 36 can be coupled to deployable member 34 at a distal end 38, or at any physical location of deployable member 34. In this manner, temperature and/or impedance is measured or monitored at a distal portion of tissue site 28 or at any position in or external to tissue site 28.

Deployable member 34 is deployable from distal end 14 of introducer 12 with less curvature than electrodes 18 and 20. Deployable member 34 can be deployable from distal end 14 without substantially any curvature.

Sensor 36 permits accurate measurement of temperature at tissue site 28 in order to determine, (i) the extent of cell necrosis, (ii) the amount of cell necrosis, (iii) whether or not further cell necrosis is needed and (iv) the boundary or periphery of the ablated mass. Further, sensor 36 reduces non-targeted tissue from being destroyed or ablated.

Sensor 36 is of conventional design, including but not limited to thermistors, thermocouples, resistive wires, and the like. A suitable thermal sensor 36 includes a T type thermocouple with copper constantene, J type, E type, K type, fiber optics, resistive wires, thermocouple IR detectors, and the like. It will be appreciated that sensor 36 need not be a thermal sensor.

Sensor 36 measures temperature and/or impedance to permit monitoring and a desired level of cell necrosis to be achieved without destroying too much tissue. This reduces damage to tissue surrounding the targeted mass to be ablated. By monitoring the temperature at various points within and outside of the interior of tissue site 28, a determination of the selected tissue mass periphery can be made, as well as a determination of when cell necrosis is complete. If at any time sensor 36 determines that a desired cell necrosis temperature is exceeded, then an appropriate feedback signal is received at an energy source 40 coupled to energy delivery device 16 which then regulates the amount of electromagnetic energy delivered to electrodes 18 and 20.

Energy source 40 can be an RF power supply, an ultrasound energy source, a microwave generator, a resistive heating source, a laser and the like. Microwave antenna, optical fibers, resistive heating elements and ultrasound transducers can be substituted for electrodes 18 and 20. When energy source 40 is an RF power supply, 5 to 200 watts, preferably 5 to 100, and still more preferably 5 to 50 watts of electromagnetic energy is delivered from energy source 40 to the electrodes of energy delivery device 16 without impeding out the electrodes.

Electrodes 18 and 20 are electromagnetically coupled to energy source 40. The coupling can be direct from energy source 40 to each electrode 18 and 20 respectively, or indirect by using a collet, sleeve and the like which couples one or more electrodes to energy source 40.

Referring now to Figure 2(a), another embodiment of apparatus 10 is shown. Apparatus 10 includes a first set 42 of RF electrodes and a second set 44 of RF electrodes. First and second sets 42 and 44 can include one, two, three, four, five, etc, number of RF electrodes. As illustrated in Figure

2, first set 42 includes electrodes 46 and 48, and second set 44 includes electrodes 50 and 52. It will be appreciated that first and second sets 42 and 44 can include more or less electrodes than are illustrated in Figure 2.

Electrodes 46, 48, 50 and 52 have tissue piercing distal ends, are positionable in introducer 12 in compacted states, and advanceable to deployed states from distal end 14 with curvature from introducer 12. First set 42 is deployable a greater distance from distal end 14 than second set 44.

First and second sets 42 and 44 are coupled to electrode advancement member 30 and can be simultaneously or individually deployed from distal end 14. Optionally coupled to first set 42, second set 44 and/or electrode advancement member 30 is deployable member 34. Again, deployable member 34 can be coupled to a sensor 36 and all or a portion of deployable member 34 may be an RF electrode.

Figure 2(b) illustrates the use of multiple sensors 36. Sensors 36 can be coupled to all or some of electrodes 46, 48, 50 and/or 52 at different positions of the electrodes. In various embodiments, sensors are positioned at distal ends of electrodes 46 through 52, at positions that are adjacent to distal end 14 of introducer 12, and at sites that are somewhere intermediate between the distal and proximal portions of deployed lengths of the electrodes. Deployable member 34 can include sensors at distal and proximal portions of its deployed length in tissue site 28. The placement of sensors 36 at different locations provides a measurement of temperature and/or impedance, and a determination of the level of cell necrosis, created at tissue site 28.

As shown in Figure 3, electrodes 18, 20, 46, 48, 50 and 52, collectively "electrodes 18", can each be coupled to one or more sensors 36. Sensors 36 can be at exterior surfaces of electrodes 18 at their distal ends,

intermediate sections as well as adjacent to distal end 14 of introducer 12. Some or all of electrodes 18 and deployable member 34 may have a hollow lumen by which a variety of different fluidic medium can be introduced from proximal to distal ends. Suitable fluidic media include but are not limited to electrolytic solutions, chemotherapeutic agents, drugs, medicaments, gene therapy agents, contrast agents and the like.

Electrode 18, as well as deployable member 34, can have a variety of different geometric cross-sections. Electrodes 18 can be made of conductive solid or hollow straight wires of various shapes such as round, flat, triangular, rectangular, hexagonal, elliptical and the like. Figures 4 and 5 illustrate circular and elliptical cross-sections. In Figure 6, the cross-section has a greater length "L" than a width of "W". In Figure 7, the cross-sectional is elongated. In various embodiments, the cross-sectional has a greater length than a width in order to enhance ultrasonic viewability.

Each, a portion of all electrodes 18, as well as deployable member 34, have an exterior surface that is wholly or partially insulated and provide a non-insulated area which is an energy delivery surface. In Figure 8, two electrodes 18 include insulation 54. In the embodiment of Figure 8, insulation 54 is a sleeve that can be fixed or adjustable. The active area of electrodes 18 is non-insulated and provides an energy delivery surface 56.

In the embodiment illustrated in Figure 9, insulation 54 is formed at the exterior of electrodes 18 in circumferential patterns, leaving a plurality of energy delivery surfaces 56. Referring now to the embodiment of Figures 10 and 11, insulation 54 extends along a longitudinal exterior surface of electrodes 18. Insulation 54 can extend along a selected distance along a longitudinal length of electrodes 18 and around a selectable portion of a circumference of electrodes 18. In various embodiments, sections of

electrodes 18 can have insulation 54 along selected longitudinal lengths of electrodes 18 as well as completely surround one or more circumferential sections of electrodes 18. Insulation 54 positioned at the exterior of electrodes 18 can be varied to define any desired shape, size and geometric energy delivery surface 56.

In Figure 12, insulation 54 is disposed on only one section of a deployed length of electrodes 18. Energy delivery surfaces 56 are at distal portions of electrodes 18 as well as on longitudinal surfaces adjacent to insulation 54. In Figure 13, insulation 54 extends along a longitudinal length of electrodes 18 can face toward a central axis 58 of tissue site 28 and energy delivery surface 56 faces towards in a direction toward the central axis 58. In Figure 14, insulation 54 extends along a longitudinal length of electrodes 18 and faces away from central axis 58 with energy delivery surface 56 facing away from central axis 58. In the embodiments illustrated in Figures 12 and 13, three electrodes 18 are positioned inside or outside of a periphery of tissue site 28. It will be appreciated that any number of electrodes 18 can be deployed with and without insulation to created a selectable cell necrosis pattern.

Electrodes 18 are selectably deployable from introducer 12 with curvature to create any desired geometric area of cell necrosis. The selectable deployment is achieved by having electrodes 18 with, (i) different advancement lengths from introducer 12, (ii) different deployed geometric configurations, (iii) variations in cross-sectional geometries, (iv) selectable insulation provided at each and/or all of the deployed electrodes 18, or (v) the use of adjustable insulation.

Deployed electrodes 18 can create a variety of different geometric cell necrosis zones including but not limited to spherical, semi-spherical,

spheroid, triangular, semi-triangular, square, semi-square, rectangular, semi-rectangular, conical, semi-conical, quadrilateral, semi-quadrilateral, semi-quadrilateral, rhomboidal, semi-rhomboidal, trapezoidal, semi-trapezoidal, combinations of the preceding, geometries with non-planar sections or sides, free-form and the like.

In one embodiment, the ultrasonic visibility of electrodes 18 through is enhanced by creating a larger electrode distal end surface area 60. Surface area 60 is the amount of the electrode body that is at the distal end of electrodes 18. Referring now to Figure 15 the distal end of electrode 18 has at cut angle of at least 25°, and in another embodiment the cut angle is at least 30°. This creates a larger surface area 60. The distal end of deployable member 34 can also have these cut angles.

Referring to Figures 16 and 17, each or selected electrodes 18 and deployable member 34 can have an associated spacer 62. Spacers 62 are advanceable from distal end 14 of introducer 12 and can be coupled to advancement member 30. Spacers 62 create a physical spacing that separates the deployed electrodes 18 from each other. The spacing created by spacers 62 also forms an area in tissue site 28 where there is reduced or very little cell necrosis. Positioned within spacers 62 is an insulation 64 that electrically and electromagnetically isolates electrodes 18 from spacers 62.

As illustrates in Figures 18 and 19, apparatus 10 can include a slidable member 66 that provides an electrical connection between energy delivery 16 and energy source 40. Slidable member 66 can be advancement member 30 or a handpiece. In one embodiment, slidable member 66 has one or two electrical contact pads 68 which can be resistor strips. When slidable member is moved in a distal direction relative to distal end 14 of introducer 12 resistor strips 68 becomes engaged with a contact 70 (Figure

18). Contact 70 is coupled to energy delivery device 16. When resistor strips 68 are engaged with contact 70, power and energy is delivered from energy source to electrodes 18. Slidable member 66 is then moved in a distal direction and resistor strips become un-engaged with contact 70 and the delivery of power from energy source 40 is disrupted (Figure 19). The employment of slidable member 66 provides a convenient energy delivery device 16 on and off mechanism at the hand of the physician.

Resistor strips 68 can be used as sensors to recognize a variable setting of one or all of electrodes 18 of energy delivery device 16. Resistor strips 68 can be used to measure resistance at a setting so that a change in the resistance value can be measured as slidable member 66 is moved and a corresponding change in the energy delivery surface corresponding to the electrodes 18. The resistance value can be correlated to determine an optimal power in delivering energy from energy source 40. Gap sensors, including but not limited to lasers and ultrasound, can be used to determine the variable setting.

Referring now to Figure 20, a feedback control system 72 is connected to energy source 40, sensors 36 and energy delivery device 16. Feedback control system 72 receives temperature or impedance data from sensors 36 and the amount of electromagnetic energy received by energy delivery device 16 is modified from an initial setting of cell necrosis energy output, cell necrosis time, temperature, and current density (the "Four Parameters"). Feedback control system 72 can automatically change any of the Four Parameters. Feedback control system 72 can detect impedance or temperature and change any of the Four Parameters. Feedback control system 72 can include a multiplexer to multiplex different electrodes 18 and a temperature detection circuit that provides a control signal representative

of temperature or impedance detected at one or more sensors 36. A microprocessor can be connected to the temperature control circuit.

The user of apparatus 10 can input an impedance value which corresponds to a setting position located at apparatus 10. Based on this value, along with measured impedance values, feedback control system 72 determines an optimal power and time need in the delivery of RF energy. Temperature is also sensed for monitoring and feedback purposes. Temperature can be maintained to a certain level by having feedback control system 72 adjust the power output automatically to maintain that level.

In another embodiment, feedback control system 72 determines an optimal power and time for a baseline setting. Ablation volumes or lesions are formed at the baseline first. Larger lesions can be obtained by extending the time of ablation after a center core is formed at the baseline. A completion of lesion creation can be checked by advancing energy delivery device 16 from distal end 14 of introducer 12 to a desired lesion size and by monitoring the temperature at the periphery of the lesion.

In another embodiment, feedback control system 72 is programmed so the delivery of energy to energy delivery device 16 is paused at certain intervals at which time temperature is measured. By comparing measured temperatures to desired temperatures feedback control system 72 can terminate or continue the delivery of power to electrodes 18 for an appropriate length of time.

The following discussion pertains particularly to the use of an RF energy source and RF electrodes but applies to other energy delivery devices and energy sources including but not limited to microwave, ultrasound, resistive heating, coherent and incoherent light, and the like.

Current delivered to electrodes 18 is measured by a current sensor 74. Voltage is measured by voltage sensor 76. Impedance and power are then calculated at power and impedance calculation device 78. These values can then be displayed at user interface and display 80. Signals
5 representative of power and impedance values are received by controller 82.

A control signal is generated by controller 82 that is proportional to the difference between an actual measured value, and a desired value. The control signal is used by power circuits 84 to adjust the power output in an appropriate amount in order to maintain the desired power delivered at
10 energy delivery device 16.

In a similar manner, temperatures detected at sensors 36 provide feedback for determining the extent of cell necrosis, and when a completed cell necrosis has reached the physical location of sensors 36. The actual temperatures are measured at temperature measurement device 86 and the
15 temperatures are displayed at user interface and display 80. A control signal is generated by controller 82 that is proportional to the difference between an actual measured temperature, and a desired temperature. The control signal is used by power circuits 84 to adjust the power output in an appropriate amount in order to maintain the desired temperature delivered at
20 the respective sensor 36. A multiplexer can be included to measure current, voltage and temperature, at the numerous sensors 36, and energy is delivered to energy delivery device 16. A variable electrode setting 88 is coupled to controller 82.

Controller 82 can be a digital or analog controller, or a computer
25 with software. When controller 82 is a computer it can include a CPU coupled through a system bus. On this system can be a keyboard, a disk drive, or other non-volatile memory systems, a display, and other

peripherals, as are known in the art. Also coupled to the bus are a program memory and a data memory.

User interface and display 80 includes operator controls and a display. Controller 82 can be coupled to imaging systems, including but not limited to ultrasound, CT scanners, X-ray, MRI, mammographic X-ray and the like. Further, direct visualization and tactile imaging can be utilized.

The output of current sensor 74 and voltage sensor 76 is used by controller 82 to maintain a selected power level at energy delivery device 16. The amount of RF energy delivered controls the amount of power. A profile of power delivered can be incorporated in controller 82, and a preset amount of energy to be delivered can also be profiled.

Circuitry, software and feedback to controller 82 result in process control, and the maintenance of the selected power, and are used to change, (i) the selected power, including RF, microwave, laser and the like, (ii) the duty cycle (on-off and wattage), (iii) bi-polar or mono-polar energy delivery and (iv) infusion medium delivery, including flow rate and pressure. These process variables are controlled and varied, while maintaining the desired delivery of power independent of changes in voltage or current, based on temperatures monitored at sensors 36.

Referring now to Figure 21, current sensor 74 and voltage sensor 76 are connected to the input of an analog amplifier 90. Analog amplifier 90 can be a conventional differential amplifier circuit for use with sensors 36. The output of analog amplifier 90 is sequentially connected by an analog multiplexer 46 to the input of A/D converter 92. The output of analog amplifier 90 is a voltage which represents the respective sensed temperatures. Digitized amplifier output voltages are supplied by A/D converter 92 to a microprocessor 96. Microprocessor 96 may be Model No.

68HCII available from Motorola. However, it will be appreciated that any suitable microprocessor or general purpose digital or analog computer can be used to calculate impedance or temperature.

5 Microprocessor 96 sequentially receives and stores digital representations of impedance and temperature. Each digital value received by microprocessor 96 corresponds to different temperatures and impedances.

10 Calculated power and impedance values can be indicated on user interface and display 80. Alternatively, or in addition to the numerical indication of power or impedance, calculated impedance and power values can be compared by microprocessor 96 with power and impedance limits. When the values exceed predetermined power or impedance values, a warning can be given on user interface and display 80, and additionally, the delivery of RF energy can be reduced, modified or interrupted. A control
15 signal from microprocessor 96 can modify the power level supplied by energy source 40.

The foregoing description of a preferred embodiment of the invention has been presented for purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise forms
20 disclosed. Obviously, many modifications and variations will be apparent to practitioners skilled in this art. It is intended that the scope of the invention be defined by the following claims and their equivalents.

What is claimed is:

CLAIMS

1 1. A cell necrosis apparatus, comprising:
2 an introducer with a distal end sufficiently sharp to penetrate tissue;
3 and
4 an energy delivery device including a first set of RF electrodes, a
5 second set of RF electrodes and a third RF electrode all having a tissue
6 piercing distal end and positionable in the introducer as the introducer is
7 advanced through tissue, the first and second sets of RF electrodes being
8 deployable with curvature from the introducer, the third RF electrode being
9 deployable from the introducer with less curvature than the first and second
10 sets of RF electrodes, wherein the second set of RF electrodes is deployable
11 a greater distance than the first set of RF electrodes from the introducer.

1 2. The apparatus of claim 1, wherein the third electrode is
2 deployable from the introducer substantially without curvature.

1 3. The apparatus of claim 1, further comprising:
2 an RF electrode advancement member coupled to the first set of RF
3 electrodes, the second set of RF electrodes and the third RF electrode

1 4. The apparatus of claim 1, wherein the introducer is
2 configured to receive a fluidic medium.

1 5. The apparatus of claim 1, further comprising:
2 an insulator positioned in a surrounding relation to at least a portion
3 of the introducer.

1 6. The apparatus of claim 1, further comprising:

2 an insulator positioned in a surrounding relation to at least a portion
3 of the first and second sets of RF electrodes.

1 7. The apparatus of claim 1, further comprising:
2 a sensor coupled to one of an electrode of the first set of RF
3 electrodes.

1 8. The apparatus of claim 1, further comprising:
2 a sensor coupled to one of an electrode of the second set of RF
3 electrodes.

1 9. The apparatus of claim 1, further comprising:
2 a sensor coupled to the third RF electrode.

1 10. The apparatus of claim 1, further comprising:
2 a sensor coupled to the introducer.

1 11. The apparatus of claim 1, further comprising:
2 a sensor coupled to the energy delivery device.

1 12. The apparatus of claim 1, wherein each electrode of the first
2 set of RF electrodes is formed of a shaped memory alloy.

1 13. The apparatus of claim 12, wherein each electrode of the
2 second set of RF electrodes is formed of a shape memory alloy.

1 14. The apparatus of claim 11, further comprising:

2 a feedback control coupled to the sensor and the energy delivery
3 device.

1 15. The apparatus of claim 1, further comprising:
2 an impedance measurement apparatus.

1 16. The apparatus of claim 15, wherein the impedance
2 measurement apparatus comprises:
3 a controller;
4 a microprocessor coupled to the controller; and
5 a feedback control including circuitry, wherein RF energy is
6 delivered to a tissue site, a measurement of a voltage and current of a tissue
7 site are determined and the current adjusted according to the measurement
8 of the voltage and current of the tissue site.

1 17. The apparatus of claim 1, wherein the introducer is a flexible
2 introducer.

1 18. The apparatus of claim 1, wherein at least a portion of the
2 introducer is an energy delivery device.

1 19. The apparatus of claim 1, wherein a distal portion of the
2 introducer is an RF electrode.

3 20. A cell necrosis apparatus, comprising:
4 an introducer including a lumen and a distal end sufficiently sharp to
5 penetrate tissue;

6 an energy delivery device including a first RF electrode with a tissue
7 piercing distal portion and a second RF electrode with a tissue piercing
8 distal portion, the first and second RF electrodes being positionable in the
9 introducer as the introducer is advanced through tissue and deployable with
10 curvature from the introducer at a selected tissue site;
11 a groundpad electrode coupled to the first and second RF electrodes;
12 and
13 a first sensor coupled to the groundpad electrode.

1 21. The apparatus of claim 20, wherein the first sensor is a
2 thermal sensor.

1 22. The apparatus of claim 20, further comprising:
2 a cooling member coupled to the groundpad electrode.

1 23. The apparatus of claim 20, further comprising:
2 an RF electrode advancement member coupled to the first and
3 second RF electrodes and configured to advance the first and second RF
4 electrodes through tissue.

1 24. The apparatus of claim 20, wherein the introducer is
2 configured to receive a fluidic medium.

1 25. The apparatus of claim 20, wherein the first RF electrode
2 includes a hollow lumen configured to receive a fluidic medium.

1 26. The apparatus of claim 20, further comprising:

2 an insulator positioned in a surrounding relation to at least a portion
3 of the introducer.

1 27. The apparatus of claim 20, further comprising:
2 an insulator positioned in a surrounding relation to at least a portion
3 of the first RF electrode.

1 28. The apparatus of claim 20, further comprising:
2 an insulator positioned in a surrounding relation to at least a portion
3 of the second RF electrode and an insulator positioned in a surrounding
4 relation to at least a portion of the first and second RF electrodes.

1 29. The apparatus of claim 20, further comprising:
2 an obturator.

1 30. The apparatus of claim 29, wherein the obturator has a
2 piercing distal end.

1 31. The apparatus of claim 29, wherein the obturator is
2 positionable in the elongated member.

1 32. The apparatus of claim 20, further comprising:
2 a second sensor coupled to the first RF electrode.

1 33. The apparatus of claim 20, wherein the second sensor is a
2 thermal sensor.

1 34. The apparatus of claim 20, further comprising:
2 a third sensor coupled to the introducer.

1 35. The apparatus of claim 20, wherein the first RF electrode is
2 formed of a shaped memory alloy.

1 36. The apparatus of claim 20, wherein the first RF electrode is
2 formed of stainless steel.

1 37. The apparatus of claim 20, wherein the first and second RF
2 electrodes are deployable to surround a selected tissue site.

1 38. The apparatus of claim 37, wherein the first and second RF
2 electrodes are deployable to surround a tumor.

1 39. The apparatus of claim 38, wherein the introducer is
2 introduced through the selected tissue site and the first and second RF
3 electrodes are deployable to surround the selected tissue site.

4 40. The apparatus of claim 32, further comprising:
5 a feedback control coupled to the first sensor and the first RF
6 electrode.

1 41. The apparatus of claim 20, further comprising:
2 an impedance measurement apparatus.

1 42. The apparatus of claim 41, wherein the impedance
2 measurement apparatus comprises:
3 a controller;
4 a microprocessor coupled to the controller; and
5 a feedback control including circuitry, wherein RF energy is
6 delivered to a tissue site, a measurement of a voltage and current of a tissue
7 site are determined and the current adjusted according to the measurement
8 of the voltage and current of the tissue site.

1 43. The apparatus of claim 20, wherein the introducer is a
2 flexible introducer.

1 44. The apparatus of claim 20, wherein at least a portion of the
2 introducer is an energy delivery device.

1 45. The apparatus of claim 20, wherein a distal portion of the
2 introducer is an RF electrode.

(54) Title: ELECTROSURGICAL DEVICE FOR NECROSIS INDUCTION

(57) Abstract

A cell necrosis apparatus includes an introducer with a distal end sufficiently sharp to penetrate tissue. An energy delivery device has a first set of RF electrodes, a second set of RF electrodes and a third RF electrode. Each of the electrodes has a tissue piercing distal end and is positional in the introducer as the introducer is advanced through tissue. The first and second sets of RF electrodes are deployable with curvature from the introducer. The third RF electrode is deployable from the introducer with less curvature than the first and second sets of RF electrodes. The second set of RF electrodes is deployable a greater distance from the introducer than the first set of RF electrodes.

ELECTROSURGICAL DEVICE FOR NECROSIS INDUCTION

BACKGROUND OF THE INVENTIONField of the Invention

5 This invention relates generally to a cell necrosis apparatus, and more particularly to a cell necrosis apparatus with an introducer and deployable electrodes.

Description of the Related Art

10 Current open procedures for treatment of tumors are extremely disruptive and cause a great deal of damage to healthy tissue. During the surgical procedure, the physician must exercise care in not cutting the tumor in a manor that creates seeding of the tumor, resulting in metastasis. In recent years, development of products has been directed with an emphasis on minimizing the traumatic nature of traditional surgical procedures.

15 There has been a relatively significant amount of activity in the area of hyperthermia as a tool for treatment of tumors. It is known that elevating the temperature of tumors is helpful in the treatment and management of cancerous tissues. The mechanisms of selective cancer cell eradication by hyperthermia are not completely understood. However, four cellular effects of hyperthermia on cancerous tissue have been proposed, (i) changes in cell
20 or nuclear membrane permeability or fluidity, (ii) cytoplasmic lysosomal disintegration, causing release of digestive enzymes, (iii) protein thermal damage affecting cell respiration and the synthesis of DNA or RNA and (iv) potential excitation of immunologic systems. Treatment methods for applying heat to tumors include the use of direct contact radio-frequency

(RF) applicators, microwave radiation, inductively coupled RF fields, ultrasound, and a variety of simple thermal conduction techniques.

Among the problems associated with all of these procedures is the requirement that highly localized heat be produced at depths of several centimeters beneath the surface of the skin.

Attempts to use interstitial local hyperthermia have not proven to be very successful. Results have often produced nonuniform temperatures throughout the tumor. It is believed that tumor mass reduction by hyperthermia is related to thermal dose. Thermal dose is the minimum effective temperature applied throughout the tumor mass for a defined period of time. Because blood flow is the major mechanism of heat loss for tumors being heated, and blood flow varies throughout the tumor, more even heating of tumor tissue is needed to ensure effective treatment.

The same is true for ablation of the tumor itself through the use of RF energy. Different methods have been utilized for the RF ablation of masses such as tumors. Instead of heating the tumor it is ablated through the application of energy. This process has been difficult to achieve due to a variety of factors including, (i) positioning of the RF ablation electrodes to effectively ablate all of the mass, (ii) introduction of the RF ablation electrodes to the tumor site and (iii) controlled delivery and monitoring of RF energy to achieve successful ablation without damage to non-tumor tissue.

Thus, non-invasive procedures for providing heat to internal tissue have had difficulties in achieving substantial specific and selective treatment.

Examples illustrating the use of electromagnetic energy to ablate tissue are disclosed in: U.S. Patent No. 4,562,200; U.S. Patent No.

4,411,266; U.S. Patent No. 4,838,265; U.S. Patent No. 5,403,311; U.S. Patent No. 4,011,872; U.S. Patent No. 5,385, 544; and U.S. Patent No. 5,385,544.

5 There is a need for a cell necrosis apparatus with at least two electrodes that are deployable with curvature from an introducer. There is another need for a cell necrosis apparatus with at least two electrodes that are selectably deployable with curvature from an introducer to a desired deployed geometric configuration. There is yet a further need for a cell necrosis apparatus that provides deployable electrodes that create a variety
10 of different geometric cell necrosis lesions.

SUMMARY OF THE INVENTION

Accordingly, an object of the invention is to provide a cell necrosis apparatus that provides tissue reduction at selected anatomical sites.

Another object of the invention is to provide a treatment apparatus to
5 create cell necrosis.

Still another object of the invention is to provide a cell necrosis apparatus that has at least two electrodes which are deployable from an introducer with curvature and a third electrode which is deployable with minimal curvature.

10 Yet another object of the invention is to provide a cell necrosis apparatus with selectively deployed electrodes.

A further object of the invention is to provide a cell necrosis apparatus that is configured to deploy electrodes selectively at a tissue site to create a desired cell necrosis lesion.

15 These and other objects of the invention are achieved in a cell necrosis apparatus including an introducer with a distal end sufficiently sharp to penetrate tissue. An energy delivery device has a first set of RF electrodes, a second set of RF electrodes and a third RF electrode. Each of electrodes has a tissue piercing distal end and is positionable in the
20 introducer as the introducer is advanced through tissue. The first and second sets of RF electrodes are deployable with curvature from the introducer. The third RF electrode is deployable from the introducer with less curvature than the first and second sets of RF electrodes. The second set of RF electrodes is deployable a greater distance from the introducer than
25 the first set of RF electrodes.

In another embodiment, a cell necrosis apparatus has an energy delivery device that includes a first RF electrode with a tissue piercing distal

portion and a second RF electrode with a tissue piercing distal portion. The first and second RF electrodes are positionable in the introducer as the introducer is advanced through tissue and deployable with curvature from the introducer at a selected tissue site. A groundpad electrode is coupled to the first and second RF electrodes. A first sensor is coupled to the groundpad electrode.

DETAILED DESCRIPTION

Referring to Figure 1, one embodiment of a cell necrosis apparatus includes an introducer 12 with a distal end 14 sufficiently sharp to penetrate tissue. An energy delivery device, generally denoted as 16, includes a first RF electrode 18 and a second RF electrode 20. Electrodes 18 and 20 are positionable in introducer 12 as introducer 12 advances through tissue. Electrodes 18 and 20 have tissue piercing distal ends 22 and 24, respectively. Electrodes 18 and 20 are selectably deployed with curvature from a distal end 14 or a side port formed in a distal portion 26 of introducer 12 to a selected tissue site 28. Tissue site 28 can be any tissue mass and can be a tumor to be ablated. Electrodes 18 and 20 are selectably deployed to be controllably positioned at a desired location relative to tissue

site 28 that includes internal placement, external placement at a periphery of tissue site 28 and at any desired location relative to tissue site 28. The selectable deployment of electrodes 18 and 20 can be achieved with the amount of advancement of electrodes 18 and 20 from introducer 12, independent advancement of electrodes 18 and 20 from introducer 12, the lengths and/or sizes of energy delivery surfaces of electrodes 18 and 20, the variation in materials used for electrodes 18 and 20 as well as variation of geometric configuration of electrodes 18 and 20 in their deployed states.

Electrodes 18 and 20 are in compacted positions while they are positioned in introducer 12. As electrodes 18 and 20 are advanced from introducer 12 they move to a deployed state from their compacted configurations. Any number of electrodes can be included in energy delivery device 16. The electrodes of energy delivery device 16 can be deployed simultaneously, in pairs, in sets and one at a time. An electrode advancement member 30 is coupled to energy delivery device 16. Electrode advancement member 30 can be actuated by the physician by movement of a proximal end 32 relative to a longitudinal axis of introducer 12.

Introducer 12 can be flexible. In one embodiment, introducer 12 is sufficiently flexible to pierce tissue, and move in any desired direction through tissue to tissue site 28. In another embodiment, introducer 12 is sufficiently flexible to reverse its direction of travel and move in direction back upon itself. In one embodiment, introducer 12 is more flexible than electrodes 18 and 20.

When introducer 12 reaches tissue site 28, including but not limited to a solid lesion, energy delivery device 16 is deployed preferably from distal end 14 of introducer 12. Energy delivery device 16 can also be deployed from side ports formed in the body of introducer 12. In the

deployed state energy delivery device 16 becomes expanded from its compacted configuration in introducer 12 and is selectively positioned relative to tissue site 12. Electrodes 18 and 20 can be positioned within an interior of tissue site 12, at the exterior of tissue site 12 as well as combinations thereof. Electrodes 18, 20 as well as third, fourth, fifth, etc. electrodes are advanceable different lengths from distal end 14 of introducer 12. In one embodiment, the electrodes of deployed energy delivery device 16 are positioned equally distant a central axis of tissue site 28. Volumetric cell necrosis can proceed from the interior, exterior of tissue site 28 as well as various combinations thereof with each deployed electrode of energy delivery device 16 in order to create a selectable and predictable cell necrosis.

Electrodes 18 and 20 can be made of a variety of conductive materials, both metallic and non-metallic. One suitable material is type 304 stainless steel of hypodermic quality. In some applications, all or a portion of electrodes 18 and 20 can be made of a shaped memory metal, such as NiTi, commercially available from Raychem Corporation, Menlo Park, California. A radiopaque marker 21 can be coated on electrodes 18 and 20 for visualization purposes.

Electrodes 18 and 20 can have different lengths that are advanced from distal end 14 of introducer 12. The lengths can be determined by the actual physical length of electrodes 18 and 20, the length of an energy delivery surface of electrodes 18 and 20 and the length of electrodes 18 and 20 that is not covered by an insulator. Suitable lengths include but are not limited to 17.5 cm, 25.0 cm. and 30.0 cm. The actual lengths of electrodes 18 and 20 depends on the location of tissue site 28 to be ablated, its distance

from the skin, its accessibility as well as whether or not the physician chooses a laparoscopic, percutaneous or other procedure.

A deployable member 34 can be coupled to electrode advancement member 30. Deployable member 34 can provide a variety of different functions including but not limited to the placement of a sensor at a selected tissue site to measure/monitor temperature and/or impedance. Additionally, all or a portion of deployable member 34 can be an RF electrode operable in bi-polar or mono-polar modes. Deployable member 34 can also be a groundpad electrode.

A sensor 36 can be coupled to deployable member 34 at a distal end 38, or at any physical location of deployable member 34. In this manner, temperature and/or impedance is measured or monitored at a distal portion of tissue site 28 or at any position in or external to tissue site 28.

Deployable member 34 is deployable from distal end 14 of introducer 12 with less curvature than electrodes 18 and 20. Deployable member 34 can be deployable from distal end 14 without substantially any curvature.

Sensor 36 permits accurate measurement of temperature at tissue site 28 in order to determine, (i) the extent of cell necrosis, (ii) the amount of cell necrosis, (iii) whether or not further cell necrosis is needed and (iv) the boundary or periphery of the ablated mass. Further, sensor 36 reduces non-targeted tissue from being destroyed or ablated.

Sensor 36 is of conventional design, including but not limited to thermistors, thermocouples, resistive wires, and the like. A suitable thermal sensor 36 includes a T type thermocouple with copper constantene, J type, E type, K type, fiber optics, resistive wires, thermocouple IR detectors, and the like. It will be appreciated that sensor 36 need not be a thermal sensor.

Sensor 36 measures temperature and/or impedance to permit monitoring and a desired level of cell necrosis to be achieved without destroying too much tissue. This reduces damage to tissue surrounding the targeted mass to be ablated. By monitoring the temperature at various points within and outside of the interior of tissue site 28, a determination of the selected tissue mass periphery can be made, as well as a determination of when cell necrosis is complete. If at any time sensor 36 determines that a desired cell necrosis temperature is exceeded, then an appropriate feedback signal is received at an energy source 40 coupled to energy delivery device 16 which then regulates the amount of electromagnetic energy delivered to electrodes 18 and 20.

Energy source 40 can be an RF power supply, an ultrasound energy source, a microwave generator, a resistive heating source, a laser and the like. Microwave antenna, optical fibers, resistive heating elements and ultrasound transducers can be substituted for electrodes 18 and 20. When energy source 40 is an RF power supply, 5 to 200 watts, preferably 5 to 100, and still more preferably 5 to 50 watts of electromagnetic energy is delivered from energy source 40 to the electrodes of energy delivery device 16 without impeding out the electrodes.

Electrodes 18 and 20 are electromagnetically coupled to energy source 40. The coupling can be direct from energy source 40 to each electrode 18 and 20 respectively, or indirect by using a collet, sleeve and the like which couples one or more electrodes to energy source 40.

Referring now to Figure 2(a), another embodiment of apparatus 10 is shown. Apparatus 10 includes a first set 42 of RF electrodes and a second set 44 of RF electrodes. First and second sets 42 and 44 can include one, two, three, four, five, etc, number of RF electrodes. As illustrated in Figure

2, first set 42 includes electrodes 46 and 48, and second set 44 includes electrodes 50 and 52. It will be appreciated that first and second sets 42 and 44 can include more or less electrodes than are illustrated in Figure 2.

Electrodes 46, 48, 50 and 52 have tissue piercing distal ends, are positionable in introducer 12 in compacted states, and advanceable to deployed states from distal end 14 with curvature from introducer 12. First set 42 is deployable a greater distance from distal end 14 than second set 44.

First and second sets 42 and 44 are coupled to electrode advancement member 30 and can be simultaneously or individually deployed from distal end 14. Optionally coupled to first set 42, second set 44 and/or electrode advancement member 30 is deployable member 34. Again, deployable member 34 can be coupled to a sensor 36 and all or a portion of deployable member 34 may be an RF electrode.

Figure 2(b) illustrates the use of multiple sensors 36. Sensors 36 can be coupled to all or some of electrodes 46, 48, 50 and/or 52 at different positions of the electrodes. In various embodiments, sensors are positioned at distal ends of electrodes 46 through 52, at positions that are adjacent to distal end 14 of introducer 12, and at sites that are somewhere intermediate between the distal and proximal portions of deployed lengths of the electrodes. Deployable member 34 can include sensors at distal and proximal portions of its deployed length in tissue site 28. The placement of sensors 36 at different locations provides a measurement of temperature and/or impedance, and a determination of the level of cell necrosis, created at tissue site 28.

As shown in Figure 3, electrodes 18, 20, 46, 48, 50 and 52, collectively "electrodes 18", can each be coupled to one or more sensors 36. Sensors 36 can be at exterior surfaces of electrodes 18 at their distal ends,

intermediate sections as well as adjacent to distal end 14 of introducer 12. Some or all of electrodes 18 and deployable member 34 may have a hollow lumen by which a variety of different fluidic medium can be introduced from proximal to distal ends. Suitable fluidic media include but are not limited to electrolytic solutions, chemotherapeutic agents, drugs, medicaments, gene therapy agents, contrast agents and the like.

Electrode 18, as well as deployable member 34, can have a variety of different geometric cross-sections. Electrodes 18 can be made of conductive solid or hollow straight wires of various shapes such as round, flat, triangular, rectangular, hexagonal, elliptical and the like. Figures 4 and 5 illustrate circular and elliptical cross-sections. In Figure 6, the cross-section has a greater length "L" than a width of "W". In Figure 7, the cross-sectional is elongated. In various embodiments, the cross-sectional has a greater length than a width in order to enhance ultrasonic viewability.

Each, a portion of all electrodes 18, as well as deployable member 34, have an exterior surface that is wholly or partially insulated and provide a non-insulated area which is an energy delivery surface. In Figure 8, two electrodes 18 include insulation 54. In the embodiment of Figure 8, insulation 54 is a sleeve that can be fixed or adjustable. The active area of electrodes 18 is non-insulated and provides an energy delivery surface 56.

In the embodiment illustrated in Figure 9, insulation 54 is formed at the exterior of electrodes 18 in circumferential patterns, leaving a plurality of energy delivery surfaces 56. Referring now to the embodiment of Figures 10 and 11, insulation 54 extends along a longitudinal exterior surface of electrodes 18. Insulation 54 can extend along a selected distance along a longitudinal length of electrodes 18 and around a selectable portion of a circumference of electrodes 18. In various embodiments, sections of

electrodes 18 can have insulation 54 along selected longitudinal lengths of electrodes 18 as well as completely surround one or more circumferential sections of electrodes 18. Insulation 54 positioned at the exterior of electrodes 18 can be varied to define any desired shape, size and geometric energy delivery surface 56.

In Figure 12, insulation 54 is disposed on only one section of a deployed length of electrodes 18. Energy delivery surfaces 56 are at distal portions of electrodes 18 as well as on longitudinal surfaces adjacent to insulation 54. In Figure 13, insulation 54 extends along a longitudinal length of electrodes 18 can face toward a central axis 58 of tissue site 28 and energy delivery surface 56 faces towards in a direction toward the central axis 58. In Figure 14, insulation 54 extends along a longitudinal length of electrodes 18 and faces away from central axis 58 with energy delivery surface 56 facing away from central axis 58. In the embodiments illustrated in Figures 12 and 13, three electrodes 18 are positioned inside or outside of a periphery of tissue site 28. It will be appreciated that any number of electrodes 18 can be deployed with and without insulation to created a selectable cell necrosis pattern.

Electrodes 18 are selectably deployable from introducer 12 with curvature to create any desired geometric area of cell necrosis. The selectable deployment is achieved by having electrodes 18 with, (i) different advancement lengths from introducer 12, (ii) different deployed geometric configurations, (iii) variations in cross-sectional geometries, (iv) selectable insulation provided at each and/or all of the deployed electrodes 18, or (v) the use of adjustable insulation.

Deployed electrodes 18 can create a variety of different geometric cell necrosis zones including but not limited to spherical, semi-spherical,

spheroid, triangular, semi-triangular, square, semi-square, rectangular, semi-rectangular, conical, semi-conical, quadrilateral, semi-quadrilateral, semi-quadrilateral, rhomboidal, semi-rhomboidal, trapezoidal, semi-trapezoidal, combinations of the preceding, geometries with non-planar sections or sides, free-form and the like.

In one embodiment, the ultrasonic visibility of electrodes 18 through is enhanced by creating a larger electrode distal end surface area 60. Surface area 60 is the amount of the electrode body that is at the distal end of electrodes 18. Referring now to Figure 15 the distal end of electrode 18 has at cut angle of at least 25°, and in another embodiment the cut angle is at least 30°. This creates a larger surface area 60. The distal end of deployable member 34 can also have these cut angles.

Referring to Figures 16 and 17, each or selected electrodes 18 and deployable member 34 can have an associated spacer 62. Spacers 62 are advanceable from distal end 14 of introducer 12 and can be coupled to advancement member 30. Spacers 62 create a physical spacing that separates the deployed electrodes 18 from each other. The spacing created by spacers 62 also forms an area in tissue site 28 where there is reduced or very little cell necrosis. Positioned within spacers 62 is an insulation 64 that electrically and electromagnetically isolates electrodes 18 from spacers 62.

As illustrates in Figures 18 and 19, apparatus 10 can include a slidable member 66 that provides an electrical connection between energy delivery 16 and energy source 40. Slidable member 66 can be advancement member 30 or a handpiece. In one embodiment, slidable member 66 has one or two electrical contact pads 68 which can be resistor strips. When slidable member is moved in a distal direction relative to distal end 14 of introducer 12 resistor strips 68 becomes engaged with a contact 70 (Figure

18). Contact 70 is coupled to energy delivery device 16. When resistor strips 68 are engaged with contact 70, power and energy is delivered from energy source to electrodes 18. Slidable member 66 is then moved in a distal direction and resistor strips become un-engaged with contact 70 and the delivery of power from energy source 40 is disrupted (Figure 19). The employment of slidable member 66 provides a convenient energy delivery device 16 on and off mechanism at the hand of the physician.

Resistor strips 68 can be used as sensors to recognize a variable setting of one or all of electrodes 18 of energy delivery device 16. Resistor strips 68 can be used to measure resistance at a setting so that a change in the resistance value can be measured as slidable member 66 is moved and a corresponding change in the energy delivery surface corresponding to the electrodes 18. The resistance value can be correlated to determine an optimal power in delivering energy from energy source 40. Gap sensors, including but not limited to lasers and ultrasound, can be used to determine the variable setting.

Referring now to Figure 20, a feedback control system 72 is connected to energy source 40, sensors 36 and energy delivery device 16. Feedback control system 72 receives temperature or impedance data from sensors 36 and the amount of electromagnetic energy received by energy delivery device 16 is modified from an initial setting of cell necrosis energy output, cell necrosis time, temperature, and current density (the "Four Parameters"). Feedback control system 72 can automatically change any of the Four Parameters. Feedback control system 72 can detect impedance or temperature and change any of the Four Parameters. Feedback control system 72 can include a multiplexer to multiplex different electrodes 18 and a temperature detection circuit that provides a control signal representative

of temperature or impedance detected at one or more sensors 36. A microprocessor can be connected to the temperature control circuit.

The user of apparatus 10 can input an impedance value which corresponds to a setting position located at apparatus 10. Based on this value, along with measured impedance values, feedback control system 72 determines an optimal power and time need in the delivery of RF energy. Temperature is also sensed for monitoring and feedback purposes. Temperature can be maintained to a certain level by having feedback control system 72 adjust the power output automatically to maintain that level.

In another embodiment, feedback control system 72 determines an optimal power and time for a baseline setting. Ablation volumes or lesions are formed at the baseline first. Larger lesions can be obtained by extending the time of ablation after a center core is formed at the baseline. A completion of lesion creation can be checked by advancing energy delivery device 16 from distal end 14 of introducer 12 to a desired lesion size and by monitoring the temperature at the periphery of the lesion.

In another embodiment, feedback control system 72 is programmed so the delivery of energy to energy delivery device 16 is paused at certain intervals at which time temperature is measured. By comparing measured temperatures to desired temperatures feedback control system 72 can terminate or continue the delivery of power to electrodes 18 for an appropriate length of time.

The following discussion pertains particularly to the use of an RF energy source and RF electrodes but applies to other energy delivery devices and energy sources including but not limited to microwave, ultrasound, resistive heating, coherent and incoherent light, and the like.

Current delivered to electrodes 18 is measured by a current sensor 74. Voltage is measured by voltage sensor 76. Impedance and power are then calculated at power and impedance calculation device 78. These values can then be displayed at user interface and display 80. Signals
5 representative of power and impedance values are received by controller 82.

A control signal is generated by controller 82 that is proportional to the difference between an actual measured value, and a desired value. The control signal is used by power circuits 84 to adjust the power output in an appropriate amount in order to maintain the desired power delivered at
10 energy delivery device 16.

In a similar manner, temperatures detected at sensors 36 provide feedback for determining the extent of cell necrosis, and when a completed cell necrosis has reached the physical location of sensors 36. The actual temperatures are measured at temperature measurement device 86 and the
15 temperatures are displayed at user interface and display 80. A control signal is generated by controller 82 that is proportional to the difference between an actual measured temperature, and a desired temperature. The control signal is used by power circuits 84 to adjust the power output in an appropriate amount in order to maintain the desired temperature delivered at
20 the respective sensor 36. A multiplexer can be included to measure current, voltage and temperature, at the numerous sensors 36, and energy is delivered to energy delivery device 16. A variable electrode setting 88 is coupled to controller 82.

Controller 82 can be a digital or analog controller, or a computer
25 with software. When controller 82 is a computer it can include a CPU coupled through a system bus. On this system can be a keyboard, a disk drive, or other non-volatile memory systems, a display, and other

peripherals, as are known in the art. Also coupled to the bus are a program memory and a data memory.

User interface and display 80 includes operator controls and a display. Controller 82 can be coupled to imaging systems, including but not limited to ultrasound, CT scanners, X-ray, MRI, mammographic X-ray and the like. Further, direct visualization and tactile imaging can be utilized.

The output of current sensor 74 and voltage sensor 76 is used by controller 82 to maintain a selected power level at energy delivery device 16. The amount of RF energy delivered controls the amount of power. A profile of power delivered can be incorporated in controller 82, and a preset amount of energy to be delivered can also be profiled.

Circuitry, software and feedback to controller 82 result in process control, and the maintenance of the selected power, and are used to change, (i) the selected power, including RF, microwave, laser and the like, (ii) the duty cycle (on-off and wattage), (iii) bi-polar or mono-polar energy delivery and (iv) infusion medium delivery, including flow rate and pressure. These process variables are controlled and varied, while maintaining the desired delivery of power independent of changes in voltage or current, based on temperatures monitored at sensors 36.

Referring now to Figure 21, current sensor 74 and voltage sensor 76 are connected to the input of an analog amplifier 90. Analog amplifier 90 can be a conventional differential amplifier circuit for use with sensors 36. The output of analog amplifier 90 is sequentially connected by an analog multiplexer 46 to the input of A/D converter 92. The output of analog amplifier 90 is a voltage which represents the respective sensed temperatures. Digitized amplifier output voltages are supplied by A/D converter 92 to a microprocessor 96. Microprocessor 96 may be Model No.

68HCII available from Motorola. However, it will be appreciated that any suitable microprocessor or general purpose digital or analog computer can be used to calculate impedance or temperature.

5 Microprocessor 96 sequentially receives and stores digital representations of impedance and temperature. Each digital value received by microprocessor 96 corresponds to different temperatures and impedances.

10 Calculated power and impedance values can be indicated on user interface and display 80. Alternatively, or in addition to the numerical indication of power or impedance, calculated impedance and power values can be compared by microprocessor 96 with power and impedance limits. When the values exceed predetermined power or impedance values, a warning can be given on user interface and display 80, and additionally, the delivery of RF energy can be reduced, modified or interrupted. A control
15 signal from microprocessor 96 can modify the power level supplied by energy source 40.

The foregoing description of a preferred embodiment of the invention has been presented for purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise forms
20 disclosed. Obviously, many modifications and variations will be apparent to practitioners skilled in this art. It is intended that the scope of the invention be defined by the following claims and their equivalents.

What is claimed is:

CLAIMS

- 1 1. A cell necrosis apparatus, comprising:
2 an introducer with a distal end sufficiently sharp to penetrate tissue;
3 and
4 an energy delivery device including a first set of RF electrodes, a
5 second set of RF electrodes and a third RF electrode all having a tissue
6 piercing distal end and positionable in the introducer as the introducer is
7 advanced through tissue, the first and second sets of RF electrodes being
8 deployable with curvature from the introducer, the third RF electrode being
9 deployable from the introducer with less curvature than the first and second
10 sets of RF electrodes, wherein the second set of RF electrodes is deployable
11 a greater distance than the first set of RF electrodes from the introducer.
- 1 2. The apparatus of claim 1, wherein the third electrode is
2 deployable from the introducer substantially without curvature.
- 1 3. The apparatus of claim 1, further comprising:
2 an RF electrode advancement member coupled to the first set of RF
3 electrodes, the second set of RF electrodes and the third RF electrode
- 1 4. The apparatus of claim 1, wherein the introducer is
2 configured to receive a fluidic medium.
- 1 5. The apparatus of claim 1, further comprising:
2 an insulator positioned in a surrounding relation to at least a portion
3 of the introducer.
- 1 6. The apparatus of claim 1, further comprising:

2 an insulator positioned in a surrounding relation to at least a portion
3 of the first and second sets of RF electrodes.

1 7. The apparatus of claim 1, further comprising:
2 a sensor coupled to one of an electrode of the first set of RF
3 electrodes.

1 8. The apparatus of claim 1, further comprising:
2 a sensor coupled to one of an electrode of the second set of RF
3 electrodes.

1 9. The apparatus of claim 1, further comprising:
2 a sensor coupled to the third RF electrode.

1 10. The apparatus of claim 1, further comprising:
2 a sensor coupled to the introducer.

1 11. The apparatus of claim 1, further comprising:
2 a sensor coupled to the energy delivery device.

1 12. The apparatus of claim 1, wherein each electrode of the first
2 set of RF electrodes is formed of a shaped memory alloy.

1 13. The apparatus of claim 12, wherein each electrode of the
2 second set of RF electrodes is formed of a shape memory alloy.

1 14. The apparatus of claim 11, further comprising:

2 a feedback control coupled to the sensor and the energy delivery
3 device.

1 15. The apparatus of claim 1, further comprising:
2 an impedance measurement apparatus.

1 16. The apparatus of claim 15, wherein the impedance
2 measurement apparatus comprises:
3 a controller;
4 a microprocessor coupled to the controller; and
5 a feedback control including circuitry, wherein RF energy is
6 delivered to a tissue site, a measurement of a voltage and current of a tissue
7 site are determined and the current adjusted according to the measurement
8 of the voltage and current of the tissue site.

1 17. The apparatus of claim 1, wherein the introducer is a flexible
2 introducer.

1 18. The apparatus of claim 1, wherein at least a portion of the
2 introducer is an energy delivery device.

1 19. The apparatus of claim 1, wherein a distal portion of the
2 introducer is an RF electrode.

3 20. A cell necrosis apparatus, comprising:
4 an introducer including a lumen and a distal end sufficiently sharp to
5 penetrate tissue;

6 an energy delivery device including a first RF electrode with a tissue
7 piercing distal portion and a second RF electrode with a tissue piercing
8 distal portion, the first and second RF electrodes being positionable in the
9 introducer as the introducer is advanced through tissue and deployable with
10 curvature from the introducer at a selected tissue site;

11 a groundpad electrode coupled to the first and second RF electrodes;
12 and
13 a first sensor coupled to the groundpad electrode.

1 21. The apparatus of claim 20, wherein the first sensor is a
2 thermal sensor.

1 22. The apparatus of claim 20, further comprising:
2 a cooling member coupled to the groundpad electrode.

1 23. The apparatus of claim 20, further comprising:
2 an RF electrode advancement member coupled to the first and
3 second RF electrodes and configured to advance the first and second RF
4 electrodes through tissue.

1 24. The apparatus of claim 20, wherein the introducer is
2 configured to receive a fluidic medium.

1 25. The apparatus of claim 20, wherein the first RF electrode
2 includes a hollow lumen configured to receive a fluidic medium.

1 26. The apparatus of claim 20, further comprising:

2 an insulator positioned in a surrounding relation to at least a portion
3 of the introducer.

1 27. The apparatus of claim 20, further comprising:
2 an insulator positioned in a surrounding relation to at least a portion
3 of the first RF electrode.

1 28. The apparatus of claim 20, further comprising:
2 an insulator positioned in a surrounding relation to at least a portion
3 of the second RF electrode and an insulator positioned in a surrounding
4 relation to at least a portion of the first and second RF electrodes.

1 29. The apparatus of claim 20, further comprising:
2 an obturator.

1 30. The apparatus of claim 29, wherein the obturator has a
2 piercing distal end.

1 31. The apparatus of claim 29, wherein the obturator is
2 positionable in the elongated member.

1 32. The apparatus of claim 20, further comprising:
2 a second sensor coupled to the first RF electrode.

1 33. The apparatus of claim 20, wherein the second sensor is a
2 thermal sensor.

1 34. The apparatus of claim 20, further comprising:
2 a third sensor coupled to the introducer.

1 35. The apparatus of claim 20, wherein the first RF electrode is
2 formed of a shaped memory alloy.

1 36. The apparatus of claim 20, wherein the first RF electrode is
2 formed of stainless steel.

1 37. The apparatus of claim 20, wherein the first and second RF
2 electrodes are deployable to surround a selected tissue site.

1 38. The apparatus of claim 37, wherein the first and second RF
2 electrodes are deployable to surround a tumor.

1 39. The apparatus of claim 38, wherein the introducer is
2 introduced through the selected tissue site and the first and second RF
3 electrodes are deployable to surround the selected tissue site.

4 40. The apparatus of claim 32, further comprising:
5 a feedback control coupled to the first sensor and the first RF
6 electrode.

1 41. The apparatus of claim 20, further comprising:
2 an impedance measurement apparatus.

1 42. The apparatus of claim 41, wherein the impedance
2 measurement apparatus comprises:
3 a controller;
4 a microprocessor coupled to the controller; and
5 a feedback control including circuitry, wherein RF energy is
6 delivered to a tissue site, a measurement of a voltage and current of a tissue
7 site are determined and the current adjusted according to the measurement
8 of the voltage and current of the tissue site.

1 43. The apparatus of claim 20, wherein the introducer is a
2 flexible introducer.

1 44. The apparatus of claim 20, wherein at least a portion of the
2 introducer is an energy delivery device.

1 45. The apparatus of claim 20, wherein a distal portion of the
2 introducer is an RF electrode.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 99/20068

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 A61B18/14

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 A61B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	WO 96 29946 A (UNIV. OF NEBRASKA) 3 October 1996 (1996-10-03) cited in the application summary of the invention ref sign 238a page 15, line 15-19; figures 5,6 ---	1-3, 11-16, 18-29
Y	WO 97 06855 A (RITA MEDICAL) 27 February 1997 (1997-02-27) the whole document ---	1,2, 4-16, 18-29
Y	US 5 685 839 A (EDWARDS) 11 November 1997 (1997-11-11) the whole document -----	3-10

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search
